Kausworth**

## **Risk Assessment**

## **5 Technical Backgrounds**

# For each site a Problem is described and three Questions to be Answered

**ENGINEERING GEOLOGY**

The site is to be excavated to a depth of 15m and requires the top 20m of ground to be defined.

Ground level on site is horizontal, and the Geological Survey map suggests it should be Quaternary alluvium overlying Carboniferous sandstone and chalk. BH data available extends to GL- 40m.

1. Establish the 3D geology for the site and present this as a 3D model for the ground either as a dimensioned sketch or a series of related vertical cross-sections.
2. Quantify the volume of alluvium that will be removed when the site is excavated to a depth of 7m.
3. Calculate the vertical effective stress at 12m below ground level at GR 10:9 if the bulk unit weight of the deposits above the sandstone =  $16\text{kN/m}^3$ , and the sandstone =  $20\text{kN/m}^3$ , when the water level is at the ground surface.

## HELP for IYA FARM

## EG4E13H

**Q. How do I quantify a volume of ground?**

Multiply its vertical thickness by its area. If the thickness of the layer is not uniform produce contour maps for its upper and lower boundary, using a 3-Point solution. These boundaries may be in different directions. Use a cross section drawn in the direction of dip of a boundary to guide you.

*Subject prompts; Strike line maps, 3-Point solution, vertical cross sections.*

**Q. How do I calculate the volume of irregular strata?**

Not all strata have a uniform thickness because their upper and lower surfaces are not parallel. This requires you to first define the shape of the volume and then to subdivide that shape into regular bodies whose volume can be calculated (wedges, prisms, cubes, etc). This is done using vertical sections at right angles to strike, i.e. in the direction of dip.

**Q. How is an interface located?**

An interface is a boundary and can be located using bore hole data and a 3-Point solution using strike lines.

**Q. What is a strike line?**

This is a contour for a geological surface joining points on it of equal elevation, like contours for ground surface on a topographic map.

The direction of maximum dip of a surface is  $90^\circ$  to its strike lines and pointing in the direction of decreasing elevation.

The direction of strike is the angle between a strike line and magnetic north; it can be measured clockwise or anticlockwise. Thus the direction of an E-W strike line is either  $N090^\circ$  or  $N270^\circ$ .

*Subject prompt; Strike lines.*

**Q. How do I produce a map of strike lines?**

By triangulation of known data points, often provided by BH logs, following the principle of the 3-Point solution.

**Q. What is the 3-Point solution?**

This is a graphical procedure based on triangulation. The position of a plane intersected by 3 vertical BH's can be recreated in space from the elevation of the plane relative to a datum common to each of those 3 BH's.

Thus the method presumes continuity of the plane and uniformity of its dip and strike.

The principle does not apply to curved surfaces but usually provides a reasonable prediction for surfaces that are not precisely planar over the dimensions of most sites.

*Subject prompt; 3-Point construction or solution.*

**Q. How do I produce an engineering cross section?**

Use squared paper. Make the horizontal and vertical scales equal. Mark on your section a datum from which to measure everything; this is a horizontal reference plane, and that usually makes ground level an inappropriate surface to use; sea level is ideal.

Locate your BH's along the line of the section at their correct spacing; use straight section lines. Plot your geology relative to datum. Join common boundaries but think; is there more than one way of joining these?

You can now predict the elevation of a surface at any place on the section; does such a prediction agree with other evidence?

*Subject prompt; Drawing cross-sections.*

**Q. Calculation of ground water pressure at depth.**

The pore water pressure (u) at depth (z) = unit weight of water ( $9.81 \text{ kN/m}^3$ ) x pressure head at z (m) =  $\text{kN/m}^2$

Pressure head at (z) = height of the column of water supported by the pressure of water at (z).

*Subject prompts; mass, acceleration, force, weight,*

*total weight = bulk weight, saturated weight,*

*submerged weight = buoyant weight, hydraulic head, hydrostatic head, pressure head.*

# Each exercise has maps, reports and photos to help you solve them

**Resources** can be changed to suite purpose

IYA FARM WALK OVER BY M. T. P. 25.03.2011  
 WEATHER: SUNNY, DRY & WINDY  
 CATTLE IN FIELD BUT THESE WILL BE CLEARED BEFORE GROUND INVESTIGATION STARTS.  
 GRASS COVER AND FIRM UNDERFOOT.  
 RAY M. P. DOLLAR = OWNER, BUT LIVES ABERCRAVIE  
 DIK WAYLAND = LAND AGENT (-58920483)  
 ACCESS THROUGH FARM (JOHN GREGGINS -94344933)  
 SITE BASICALLY FLAT, VERY GENTLE SLOPE TOWARDS RIVER VALLEY WITH SLIGHT CHANGE IN SLOPE ABOUT HALF-WAY TOWARDS RIVER. RIVER BANKS LOOK UNSTABLE AND EXPOSE SAND & GRAVEL WITH SOME CLAY. ALLUVIUM ON RIVER BANKS CONTAINS GRAVEL AND SAND OF BROWN QUARTZ, & CHERT (!), WITH COBBLES OF SHALE AND SMALLER SHALE PARTICLES DOWN TO GRIT SIZE. WATER SEEPING FROM THE SANDS AND GRAVELS EXPOSED ON THE VALLEY SIDE, INTO THE RIVER.

**Westmoreland Drilling Co Ltd BOREHOLE LOG ROTARY**

Contract No. P11748 Method: Rotary Core Logging Coordinates: 457930 E, 303000 N  
 Project: KDC mine subsidence Drill site: 150 Ground level: 20.0m  
 Client: Kiewit DC Driller: RD Orientation: vertical  
 Consultant: Thomson Co. Core length: 100m Date started: 14/01/07  
 Core desc: Top

**Description of strata**

Depth (m)	Remarks	SP100	SP500	SP1000
0-10	Upper and lower non-fossiliferous fragments of chert and fossils and concrete in heavy grey clay matrix with thin silty layers, sand and plastic shattering (MCL220220)			
10-20	Moderately dense to firm SAND with rounded pebbles of yellowish sandstone with occasional beds of coarse sandstone GRAVELS occurring every 100 mm to 2 m ALL GRAVELS	10-20	10-20	10-20
20-30	Work fine to medium bedded, grey SHALE, light brown to dark brown on bedding and bedding. Disconformity clearly marked, typically sub-angled, very, search with care for thin clay	31-33	31-33	31-33
30-50	Dark grey, moderately strong massive COAL. Coal 17-19 m thick. Thin to 1.5 m. Crushed coal with fragments of shale and other rocks with soft grey clay. (see P11748-2004)	42-50	42-50	42-50
50-55	Stony, well bedded, brown SANDSTONE, clear gradation on bedding, some horizontal fossils, beds to other occasional brown CLAY, shales, clay, rough down	51-55	51-55	51-55
55-100	Grey, clayey, medium bedded sandstone	55-100	55-100	55-100

COMMENTS: Core 17 m. Note log and rock diplog at a depth of 17 m. Shales in 17 m. No fossils in the red or contact with the COAL. (see P11748-2004)

NOTE: All depths in metres. All bearings in kilometres. See header sheet for details of drilling progress and other details. See log sheet for symbols key.

**BREANS LANDING RISK ASSESSMENT GALLERY-1**

**YOU MUST USE YOUR EDUCATION & EXPERIENCE TO PRODUCE SOUND JUDGEMENT, JUSTIFIED CONCLUSIONS & A SENSIBLE PLAN OF ACTION**

- Civil Engineering
- Environmental Science
- Engineering Geology
- Geotechnical Engineering
- Hydrogeology

There is a pattern on the outcrop of the Chalk; could it be reflecting some unknown aspect of geology?

Low dips = uncertainties with predicting strike (see Tenupy). Is the nature of the boundary between the superficial materials and the Chalk known? (see Walk-Over photos). If this site is 3km from the sea what problems could this raise?

**NORTH BREAN'S LANDING AIR PHOTO**

Much detail shown over site that is not shown on topographical and geological maps; what can it mean and is it likely to be significant?

**NORTH BREAN'S LANDING GEOLOGY MAP**

Does the river have a buried channel that connects with bedrock? If so what will this do to groundwater?

Is this river tidal? If it is what could be expected? What influence might it have on groundwater?
